

# Simultaneous Analysis of Water-Soluble Vitamins in Vitamin-Enriched Beverages and Multivitamin Dietary Supplements by UHPLC-MS/MS

Jinyuan (Leo) Wang, Xiaodong Liu, and William Schnute, Thermo Fisher Scientific, Sunnyvale, CA, USA

## Introduction

Vitamins are nutrients essential to human health, and are present in almost all types of foods. In addition to food sources, vitamin supplements are often consumed to ensure adequate vitamin intake, as a customary diet does not always provide sufficient vitamins due to bias and/or limitation in the choice of foods, or malfunctions in digestion and ingestion. Vitamin supplements are available in various forms such as single- or multivitamin tablets, formula, and vitamin-enriched beverages (VEB). Certain foods are commercially fortified with vitamins and/or other nutritional essentials such as minerals. Based on their solubility, vitamins are divided into two categories: water-soluble vitamins (WSV) and fat-soluble vitamins (FSV). WSVs include vitamin C (ascorbic acid), B<sub>1</sub> (thiamine), B<sub>2</sub> (riboflavin), B<sub>3</sub> (niacin, niacinamide), B<sub>5</sub> (pantothenic acid), B<sub>6</sub> (pyridoxine), B<sub>7</sub> (biotin), B<sub>9</sub> (folic acid), and B<sub>12</sub> (cyanocobalamin). Accurate quantitative measurements for vitamins are required to ensure product quality and regulatory compliance as well as to monitor vitamin intake.

Established methods for vitamin analysis include microbiological methods, which are typically designed for single vitamin analysis and are time consuming,<sup>1,2</sup> and chromatographic methods, including gas chromatography,<sup>3,4</sup> capillary electrophoresis,<sup>5,6</sup> and liquid chromatography (LC) with various methods of detection.<sup>7–16</sup>

LC methods are generally used for simultaneous determination of multiple vitamins of interests and for establishing vitamin profiles in a variety of matrices with various modes of detection.<sup>7–10, 13–16</sup> Here we present a high-throughput method for simultaneous determination for the above mentioned ten WSVs using ultrahigh-performance LC and tandem mass spectrometry (UHPLC-MS/MS). Chromatography was optimized for the total resolution of all target analytes on a Thermo Scientific Acclaim™ C30 reversed-phase (RP) column. An MS/MS instrument was operated in selected reaction monitoring (SRM) mode for the best selectivity and sensitivity, and an isotope labeled internal standard (IStd) was used for accurate quantitation.

Randomly selected VEBs and multivitamin supplement tablets (MVSTs) were assayed by this method for selected vitamins. Much higher values were observed for most vitamins in VEBs than product labeling. Results also showed close agreement between observed and label values for MVSTs.

## Experimental

### Chemicals and Reagents

A set of WSV standards was purchased from AccuStandard (P/N: VIT-WSK-R1-SET) containing ten individual chemicals. Isotope labeled internal standard pyridoxine-d<sub>2</sub> was purchased from C/D/N Isotopes (P/N: D-6819). Ammonium formate and formic acid were purchased from Sigma-Aldrich. Acetonitrile was obtained from Burdick & Jackson (HPLC/UV grade). Deionized water (DI H<sub>2</sub>O) was purified from a Millipore water station.

### Preparation of Standards

Individual stock solutions were prepared by dissolving an appropriate amount of pure chemical in 1% formic acid at 1 mg/mL (1000 parts per million [ppm]) unless noted. Folic acid and riboflavin were prepared in basic solution at 1000 ppm and 100 ppm respectively (basified by ammonium hydroxide, 4% and 0.7% respectively). The IStd was prepared in 1% formic acid at 10 ppm to prepare calibration standards and spike unknown samples.

Calibration standards were prepared in 0.1% formic acid and ranged from 10 ppb to 5000 ppb at 7 levels: 10 ppb, 50 ppb, 100 ppb, 500 ppb, 1000 ppb, 2000 ppb, and 5000 ppb. Target analytes were divided into three groups: Group 1 containing only B<sub>9</sub>; Group 2 containing B<sub>7</sub> and B<sub>12</sub>; and Group 3 containing B<sub>1</sub>, B<sub>2</sub>, B<sub>3</sub> (niacin and niacinamide), B<sub>5</sub>, and B<sub>6</sub>. IStd was spiked in each calibration standard at 500 ppb.

## Preparation of Vitamin-Enriched Beverage Samples

VEB samples were randomly selected and purchased from a local grocery store and kept at room temperature until analysis. Carbonated VEBs were degassed using a sonication bath for 30 seconds. A 1 mL aliquot of each sample was transferred to a 1.5 mL autosampler vial, spiked with IStd at 500 ppb, vortex mixed, and analyzed for Group 1 and Group 2 vitamins. A 10  $\mu$ L aliquot of each sample was pipetted to another 1.5 mL autosampler vial, diluted with 990  $\mu$ L DI H<sub>2</sub>O, spiked with IStd at 500 ppb, vortex mixed, and then analyzed for Group 3 vitamins.

## Preparation of Multivitamin Tablet Samples

Three bottles of multivitamin tablets were purchased from the same grocery store. Twenty tablets from each bottle were weighed to calculate average weight of one tablet in each bottle. The 20 weighed tablets were then ground to fine powder in a coffee grinder (Cuisinart, DCG-12BC) for 1 min (20 s  $\times$  3). Three subsamples from each powder sample were weighed to 0.1 g in 15 mL centrifuge tubes with exact weight recorded. Each subsample was dissolved in 10 mL DI H<sub>2</sub>O in a sonicator bath for 30 min with internal standard spiked at 500 ppb. The samples were then centrifuged for 15 min at 4000 RPM. A 1 mL aliquot of the clear supernatant was pipetted from each sample to a 1.5 mL amber autosampler vial for the analysis of Group 1 and Group 2 vitamins. A 10  $\mu$ L aliquot of supernatant from each sample was pipetted to another 1.5 mL amber autosampler vial, diluted with 990  $\mu$ L DI H<sub>2</sub>O, spiked with IStd to 500 ppb, vortex mixed, and then analyzed for Group 3 vitamins.

## UHPLC-MS/MS Analysis

UHPLC-MS/MS analysis was performed using a Thermo Scientific Dionex UltiMate™ 3000 RSLC system coupled with a Thermo Scientific TSQ Quantum Access MAX™ MS/MS instrument via a heated electrospray ionization (HESI) source. Chromatographic separation was achieved using an Acclaim C30 column (P/N: 075725, 2.1  $\times$  150 mm, 3  $\mu$ m). Mobile phase consisted of three components: A) 10 mM formate buffer (pH 4.0); B) 10 mM formate buffer (pH 3.0); and C) 90% CH<sub>3</sub>CN, 10% 10 mM formate buffer (pH 3.0). Gradient elution was used with details listed in Table 1. Flow rate was set at 0.6 mL/min and the column temperature was set at 15 °C. The MS/MS instrument was operated in SRM mode with the details listed in Table 2. The HESI ionization source parameters were set as follows: Spray Voltage (4000 V); Vaporizer Temperature (350 °C); Capillary Temperature (200 °C); Sheath Gas (40 arbitrary units) and Auxiliary Gas (60 arbitrary units).

**Table 1. Mobile Phase Gradient Events**

## Results and Discussion

### Chromatography

Although many LC methods have been reported for simultaneous analysis of WSVs, these methods usually suffer from low throughput or incomplete chromatographic resolution, and several highly hydrophilic analytes are poorly retained on the commonly used C18 RP columns. In this study, a C30 column was used to improve the retention of poorly retained analytes, such as vitamin C and thiamine. In addition, ammonium formate was buffered at two pH conditions: pH 3.0 and pH 4.0, with the higher pH buffer used in the early phase of the gradient to further improve the retention for thiamine, and the lower pH buffer used to provide complete resolution for later eluted vitamins.

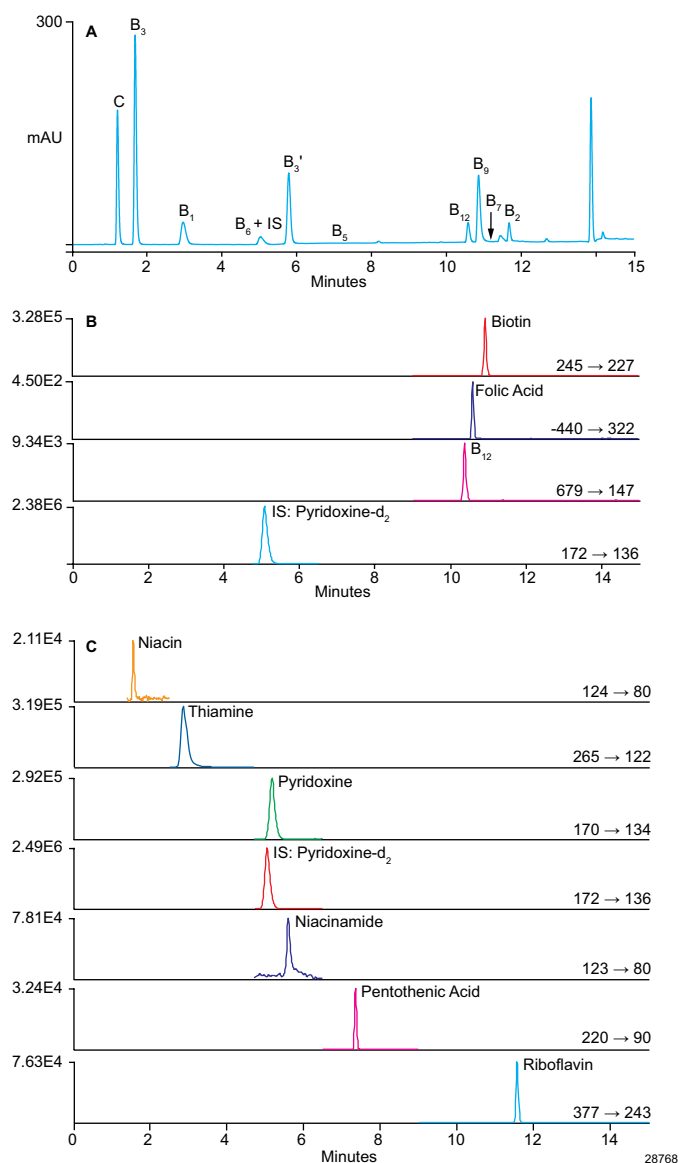

Under the optimized conditions, all target vitamins were baseline separated within 12 min. The minimum retention factor was observed for vitamin C at 1.3 (retention time 1.2 min), and the retention factor for thiamin was observed at 4.5, which was significantly improved over previously reported methods where thiamin eluted first with a retention factor of less than 1.<sup>14,15</sup> Vitamins B<sub>5</sub> and B<sub>7</sub> lack a UV chromophore and were not visible in the UV chromatogram. However, the peak labels for both analytes are shown in Figure 1A to demonstrate the chromatographic separation. These two analytes were detected by MS/MS with great sensitivity, as seen in Figure 2B and Figure 2C.

## Mass Spectrometry

Electrospray ionization (ESI) was used in this study as the ionization interface due to its suitability and better sensitivity for polar compounds than other atmospheric pressure ionization (API) techniques. Ionization source parameters for the HESI probe used in this study were optimized to provide best sensitivity and were described in the Experimental section. Under the optimized chromatographic and ionization conditions, most analytes exhibited strong protonated molecular ions (i.e.,  $[M+H]^+$ ) except for vitamin C and folic acid where deprotonated molecular ions  $[M-H]^-$  were observed as the dominant MS peak. A strong doubly-charged MS peak was observed for vitamin B<sub>12</sub> at 679  $m/z$  as well as the  $[M+H]^+$  at 1356  $m/z$ . For each analyte, the two most intense fragments were selected as the monitored product ions, which are listed in Table 2 along with the optimized collision energies. Thus for each analyte, two SRM transitions were monitored with one being quantitative SRM (Q-SRM), which showed relatively stronger MS response, and the other being confirmative SRM (C-SRM). The Q-SRM chromatograms are shown in Figure 1B and Figure 1C, with each of the vitamins at 50 ppb. The MS/MS detection demonstrated great sensitivity and selectivity for vitamin analysis even at low ppb levels. At 50 ppb, the minimum signal-to-noise ratio (S/N) was observed at 20 for niacin (26 for niacinamide) with the rest of the target analytes showing S/N greater than 100. The great sensitivity provided by MS/MS instrumentation enables the quantitation for low level vitamins such as B<sub>12</sub> and folic acid in complex matrices, which was not achievable with previously reported methods using only UV detection.

## Quantitation

One of the challenges encountered in this study was the large differences in concentration of the vitamins present in beverages or tablets. In the tested samples, the concentrations of Group 3 vitamins (mg levels per serving) were roughly 1000 times the concentrations of Group 1 and 2 vitamins ( $\mu\text{g}$  levels per serving). The lowest concentration observed was 0.6  $\mu\text{g}$  per serving ( $\text{B}_{12}$ ), while the highest concentration was at 20 mg per serving ( $\text{B}_3$ ).

A single assay trying to cover the whole concentration range is beyond the linear response range of any mass spectrometer. Two approaches are usually practiced to address this challenge among reported methods covering these wide concentration ranges. Some reported methods use MS for lower concentration analytes and less sensitive detectors such as UV for the quantitation of high concentration vitamins,<sup>14</sup> thus losing the selectivity of MS quantitation and may suffer from interferences and/or lower quantitation accuracy. Another approach performs several assays for each sample with different dilution factors and results are reported with the most appropriate dilution. In this study, the latter approach was used and two assays were performed: the primary one quantitating low concentration vitamins including  $\text{B}_7$ ,  $\text{B}_9$ , and  $\text{B}_{12}$ , which were assayed directly after spiking internal standard; and the secondary assay quantitating the remaining vitamins at higher concentrations after a 100-fold dilution and respiking the diluted sample with IStd to 500 ppb. This technique took full advantage of the selectivity and specificity provided by MS detection, thus ensuring quantitation accuracy.

Stability of vitamins in solution was another challenge. Vitamin C was extremely unstable in multivitamin solutions, and degradation was observed within 20 min even though the sample was prepared in acidic solution and placed in a thermostatted autosampler at 4 °C. Instability of the analyte itself can cause substantial variance in the quantitative determination of vitamin C, and thus it was not included for quantitation in this study. Instability was also reported for other vitamins, such as riboflavin, pyridoxine, and thiamin, which are light sensitive,<sup>17,18</sup> and thiamin, pantothenic acid (in acid or basic condition), folic acid, and pyridoxine, which are heat labile. To avoid loss of analytes during analysis, samples were prepared in amber autosampler vials and promptly placed in the refrigerated autosampler at 4 °C.

An additional challenge for accurate quantitation was the interactions of vitamins when present together in solution. Interactions between  $\text{B}_{12}$ , folic acid, and riboflavin have been reported,<sup>19-22</sup> thus targeted vitamins were divided into three groups with additional consideration of their concentrations in samples: Group 3 included higher concentration vitamins ( $\text{B}_1$ ,  $\text{B}_2$ ,  $\text{B}_3$ ,  $\text{B}_5$ , and  $\text{B}_6$ ) and Group 2 included lower concentration vitamins ( $\text{B}_7$  and  $\text{B}_{12}$ ). Although folic acid was also present in lower concentration in samples and could be included in Group 2 vitamins, observations revealed that quantitation of low concentration folic acid could be significantly interfered with by the presence of  $\text{B}_7$  and  $\text{B}_{12}$ . Thus three calibration standard sets were prepared for the three groups of vitamins to generate individual calibration curves for quantitation.

## Method Performance

Method performance was evaluated against calibrations, coefficients of determination, precision, and accuracy. Calibration curves for each analyte were generated from calibration standards with concentrations from 10 ppb to 5000 ppb at seven levels. Quadratic fits were used to fit the experimental data and  $1/x$  was used as the weighting factor. Detailed results are shown in Table 3. Excellent coefficients of correlation, precision, and accuracy were achieved for each target vitamin. Limits of quantitation (LOQs) were determined as the lowest concentration in calibration standards exhibiting signal-to-noise ratios (S/N) greater than 10. LOQ was observed at 10 ppb for most analytes, except for niacin and niacinamide at 50 ppb, and folic acid at 100 ppb. Although S/N for folic acid was achieved with values much greater than 10 at lower concentrations, poor quantitation accuracy was observed, which was believed to be the reduced stability of this analyte when present in solution at low concentration. The instruments used in this study are capable of quantification of target vitamins below the LOQs set in this method, proven by the S/N values observed at LOQ. However, this method was designed and the calibration range set to minimize sample preparation procedures, number of dilutions, and assays to be run in order to maintain a high analytical throughput.

## Analysis of Vitamin-Enriched Beverages Samples

As described in the Experimental section, ten beverage samples were selected and analyzed for their vitamin content. Among the selected beverage samples, five were vitamin-fortified water samples with different flavors, and the other five were vitamin-enriched energy drinks. The results are shown in Table 4. Large differences were observed between measured and labeled values, and this observation agreed with previously conducted studies.<sup>23,24</sup> An explanation for these discrepancies could be that the fortification was performed at levels higher than label claims, deviating in the direction of no harm,<sup>24</sup> to compensate for extrapolated degradations during storage and shelf life.

## Analysis of Multivitamin Supplement Tablet Samples

Three types of MVST samples were randomly selected and analyzed for target vitamins. Contrary to results for VEBs, the measured amounts were within good agreement to their label values, as seen in Table 5. The observed label agreement variance between beverage and tablet samples may suggest differences in vitamin stability when in different formulations, i.e., solution or tablet.

**Table 3. Calibration, Coefficient of Determination, Precision, Accuracy and Detection Limits**

Analyte		Calibration Range	r <sup>2</sup>	50 ppb*			2000 ppb			LOQ (S/N)
				Mean	% RSD	% Accuracy	Mean	% RSD	% Accuracy	
B <sub>3</sub>	Niacin	50–5000	0.9998	43.6	6.14	87.2	1960	3.34	98.0	50 (>10)

Pyridoxine	2.7 (2)	2.5 (2)	3.8 (3)
Biotin	29 (30)	25 (30)	25 (30)
Folic Acid	590 (400)	173 (400)	247 (400)
Cyanocobalamin	7.1 (6)	6.0 (6)	27 (25)

Label values of vitamins are included in parentheses.  
Duplicate assays were performed for each sample.

## Conclusion

This study describes a UHPLC-MS/MS method for simultaneous quantitation of WSVs in beverages and supplement tablets. This method demonstrated excellent correlation of determination, precision, accuracy, and selective and sensitive detection with low quantitation limits. This method was successfully applied to the determination of WSVs in beverages and supplement tablets with presented results.
